SYNOPSIS : The periodicities in the occurrence of earthquakes, as indicated by the cosmic conditions, have been traced by analysing the planetary data at the time of occurrence of more than 1100 earthquakes of magnitude, $M \geq 7.0$, which occured during the period 1896 to 1965 .

Correlation between the transits of planets in the sensitive areas and at sensitive longitudes in the zodiac and the seismicity of California and adjoining area has been shown.

Based on the analysis, a method for forecasting earthquakes is also proposed.

## INTRODUCTION

The ferocity of the devastating earthquakes has been experienced by the humanity on innumerable occasions. Attempts have been made by various researchers to correlate the terrestrial and non-terrastrial phenomena with the earthquake occurrence. The entire process is extremely complex and till this date, has defied, barring a few cases, all the attempts to successfully predict the occurrence of earthquakes. The association of non-terrestrial causes with the seismicity has been recognized for a long time (Jose, 1965 : Hedervary, 1967; Symson, 1967 and Tamrazyan, 1967). No reliable and rational method of predicting earthquakes has yet become available. Here, an attempt is made in this direction and the co-seismic planatery conditions for over one thousand global earthquakes have been studied and some conclusions drawn.

## EXISTING CONCEPTS

Raman (1968) after studying over 200 earthquakes has suggested that -
i) Only some selected relative positions of Moon with respect to Earth were found to be occurring on the days of these earthquakes.
ii) The earthquakes generally occurred at the time of eclipses and near the full Moon and New Moon days.
iii) The planets namely, Saturn, Jupiter, Rahu (Ascending Node of Moon), Mars, Mercury and Moon have been found to occupy specific relative positions amongst themselves and with respect to the place of earthquake occurrence.
iv) The time of occurrence is near mid-day, mid-night or early morning and
v) The day of occurrence is many times indicated by the transit of Mars on the
eclipse point.
According to Kharegat (1968), the charts prepared for the time of Sun's transit at $0^{\circ}-0^{\prime}-1^{\prime \prime}, 90^{\circ}-0^{\prime}-1^{\prime \prime}$, $180^{\circ}-0^{\prime}-1^{\prime \prime}$ and 270 $0^{\circ}-0^{\prime \prime}-1^{\prime \prime}$ can be successfully used for predicting the earthquakes.

Murthey (1967, 1969) has indicated certain conditions to be satisfied for the occurrence of an earthquake :
i) The Earth, the sun and the exploding supernova should align in one plane, so that the magnetic field of the supernova can influence the magnetic field of the Earth.
ii) The weak belts of the Earth's crust fall within the active magnetic plane.

It was also suggested that the effect of high energy of the cosmic rays upon the magnetic field of the Sun is affected by the pattern of the planets of the solar system.

A relation was also shown to exist between the resultant of the angular momentum of all planets and the earthquakes. A plot of the parameter related to the angular momentum of the planets with time is shown in Fig. 1 and the slope of the curve was found to change with associated major earthquakes.

Shanon (1981) has indicated certain conditions to be satisfied for occurrence of an earthquake
i) Two or more planets must occupy positions in area : $31^{\circ}$ to $60^{\circ}$ and $211^{\circ}$ to $240^{\circ}$.
ii) The difference of longitudes of two or more planets must be $0^{\circ}$ or $90^{\circ}$ or $180^{\circ}$ or $270^{\circ}$.
iii) The planetary positions associated with the time of formation of the country have

Fig. 1 Showing the Moment of the Position of $z$
been found to be related to specific planetary positions as defined in foregoing condition (ii).
iv) Presence of Mars and Venus close to each other enhances the probability of an earthquake.

Certain periods for probable occurrence, were also given (Shanon, 1981) and California earthquake of 1989 coincided with the period indicated.

Kelkar (1988) has suggested a method of forecasting earthquakes using the charts for the Solar and Lunar eclipses and the foundation charts for different countries. An earthquake is likely to occur when transiting Pluto or Uranus or Saturn or Mars or the eclipse point occupy specific positions in the foundation chart.

Dixit (1989) has shown that the eclipse point and the conjunction point for major planets are related to specific positions in the foundation chart of a country where the earthquakes occurs.

## PRESENT STUDY

From foregoing review, it is clear that the planets occupying certain relative positions with respect to the place of earthquakes and among themselves have been found to be related to positions of planets in the foundation charts of the countries in which the respective earthquake areas fall.
The objective of the present study is to scientifically scrutinise the relevant data and see if some guidelines, based on such planetary positions in relation to the earthquake areas, can be identified to help the earthquake prediction. It may be worthwhile to familiarise the reader with few terms which are used in this work.

## Zodiac

It is a $17^{\circ}$ belt - $8.5^{\circ}$ on either side of the great circle along which the sun appears to travel in the sky.

## Sensitive Area

There are the areas in the zodiac, specified with respect to the areas of earthquakes which are repeatedly occupied by the planets at the time of major earthquakes.

## Relations of Planets

The difference of apparent longitudes of two planets is generally referred to as a relation. In traditional Astrology, mainly four relations are referred. When the difference between the longitudes is $0^{\circ}$ (zero), it is called conjunction and the longitude where the conjunction takes place is referred to as conjunction point. When the difference of longitudes is $90^{\circ}$ or $270^{\circ}$, it is referred to as square relation. When the difference is $180^{\circ}$, it is called opposition. When the diff. erence is $120^{\circ}$ or $240^{\circ}$ it is called trine.

## Esclipse Point

The longitude of the sun at the time of an eclipse is called Eclipse point.

## Chart

It is the diagram in which the positions of planets are given for the date, time and place of reference. The longitude in the zodiac, rising on east horizon is called Ascendant or Ist house. The point at mid-heaven is called loth house, the point on west horizon is called 7th house and the point opposite in mid-heaven is called 4 th house.

## Aspect

Certain relations are called aspects. All the planets have opposition aspect. In western astrology, all planets have square aspect. But in Indian system, Mars can aspect $90^{\circ}$ and $210^{\circ}$ ahead, Saturn can aspect $60^{\circ}$ and $270^{\circ}$ ahead, Jupiter can aspect $120^{\circ}$ and $240^{\circ}$ ahead. Other planets can not cause any influence on such positions.

In order to formulate well defined and reliable sets of planetary configurations for the seismicity of the earth, a detail study, of the positions or relative positions of the planets at the time of occurrence of 1160 global earthquakes of magnitude, $M \geq 7.0$, which occured during the period 1896-1965 (for which the data could be collected), was undertaken.

## DATA

The seismological data i.e. the date, the time and the epicentre of the earthquake was obtained from Richter (1954, 1958), Rothe (1969) and Hedervari (1967). The astronomical data i.e. the apparent siderial longitudes (henceforth called longitudes) of the planets were calculated using condenced ephemeries by Lahiri. These data for california region pertaining to only 23 earthquakes are given in Table 1.

## DATA PROCESSING AND ANALYSIS

The position of a planet is given by the
geometric apparent longitude, latitude and

[^0]declination. Here, only the apparent longitudes were used as, consideration of other parameters would have made the work unmanagable. The positions of Saturn, Jupiter, Rahu, Mars, Sun, Venus, Mercury and Moon have been used to find out favourable planatery configurations. Though the Sun, Moon and Rahu are not planets, these will be henceforth, referred to as planets.

## Facts and Assumptions

Following facts and associated assumptions can help in grouping the planets :
i) Moon being closest to the Earth, its influence on the Earth's activity may be assumed to be more prominent.
ii) The slower moving planets may have lesser influence compared to faster moving planets.
iii) Several alternate positions of the Moon and the faster moving planets with respect to different positions of the slow moving planets will have to be studied.

Thus the planets have been divided into following three groups :

| Group A | - | Moon |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Group B | - | The | faster | moving | planets |
|  |  | Mars, | Sun, | Venus and | Mercury |
| Group C | - | The | major | or slow | w moving |
|  |  | plane | $\text { ets }-\mathrm{Sa}$ | aturn, Ju | piter and |

The average periodicities of revolution of the planets considered are as follows :

Moon - 27 days; Sun, Venus and Mercury - 1 year, Mars - 18 months; Jupiter - 12 years; Rahu 18.6 years (Rahu moves in opposite direction as compared to other planets) and Saturn 30 years.

Thus, during the period under consideration in the present study i.e. 1896-1965, Jupiter had 5 or 6 cycles for different positions, Rahu had 3 or 4 cycles and saturn had 2 or 3 cycles.

## Analysis

A combination of one planet from each of the two or three groups has been referred to as a set. For the annual transit of Saturn $\left(12^{\circ}\right.$ to $\left.18^{\circ}\right)$, Jupiter $\left(30^{\circ}\right)$ and Rahu $\left(20^{\circ}\right)$, the corresponding positions of Moon (Group A) and a selected planet (Group B) have been shown on a grid. Thus 224 grids of the various combinations, so arrived at, have been prepared. On each of these grids, the earthquakes which occurred during the corresponding periods of transists of the slow moving planets and grouped in three magnitude ranges 17.0 to 7.8 ; 7.9 to 8.5 ; and 8.6 to 8.9), are indicated. Each earthquake is represented by a point and the coordinates of the point give the positions of the Moon (Group A) and the planet in Group B. Richter's numbering of the zones on the earth has been used to represent the area of the earthquake. A typical plot is shown in Fig. 2. These plots have been examined to identify cluster of earthquakes in a zone of $30^{\circ} \times 30^{\circ}$ on the arid. The details of
the events in each of these clusters were then examined and following criterion used to pick up the significant planetary configurations. This is referred to as favourable planetary condition (condition at S.No. 19 in Table 2 is shown in Fig. 2.

Fig. 2 Grid Showing Positions of Moon (Group-A), Mars (Group-B) Corresponding to Transit of Jupiter (Group-C) at $17{ }^{-1}-1$ to $207^{-}-0^{\prime}$ for Different Farthquakes
When the set involving Saturn is associated with the occurrence of an earthquake in a minimum of two cycles and the set involving Jupiter or Rahu is associated in a minimum of three cycles, the set is assumed as $s$ favourable condition indicating a possible, occurrence of an earthquake.

In addition to the set of three planets, the association of the position of a planet of Group $C$, falling in the range not exceeding $30^{\circ}$ and the position of a planet of Group B or the difference of longitudes of the two planets falling in a range of $3^{\circ}$ was studied. Whenever a set satisfied the foregoing criteria, it was noted as a favourable condition. The study was carried out for all possible sets of two planets. Tables have been prepared (not included in this paper) showing the details of planetary position involved in favourable conditions and also the details of the associated earthquakes.

## Use of Favourable Conditions

The favourable conditions of a set of two planets or three planets indicate the probable period of occurrence of an earthquake nearest to 3 days (this is the period for transit of the Moon through $30^{\circ}$ or the period for transit of the planet of Group $B$ through $3^{\circ}$ or the period for the change of the difference in the positions of two planets of Groups $B$ and $C$ through $3^{\circ}$ ). For a set of two planets, the period can be longer if

planet of Group $B$ is in apparent retrograde motion and it can be smaller when the motion of the planet is accelerated.

* On many occasions, two or more favourable conditions occur simultaneously. The period of concurrence may be one day to a week. Whenever such concurrence is noted, an earthquake with magnitude, $M \geq 7.0$ is most likely to occur somewhere on the earth. The larger the number of favourable conditions superimposed in a small period, the larger will be the confidence level of prediction.
* When the planets occupy sensitive areas or sensitive longitudes related with the seismicity of a region, that region can expect an earthquake of magnitude, $M \geq 7.0$, in the period indicated. These sensitive areas or the sensitive longitudes can be determined by studying sufficiently larger seismic data of that area. The favourable conditions associated with the earthquakes of that area give a better idea.

## Method of Predicting Earthquakes

i. Using the data of past earthquakes of a region, the sensitive areas or sensitive longitudes are to be determined.
ii. The period of occurrence of an earthquake is to be fixed using the global favourable conditions.
iii. The correlation between the sensitive areas and sensitive longitudes for the area and the positions of planets involved in favourable conditions may help predicting an earthquake in the area, during the period indicated.

## SEISMICITY OF CALTFORNIA REGION

The seismicity of California and region around, bounded by $32^{\circ} \mathrm{N}$ to $41^{\circ} \mathrm{N}$ and $115^{\circ} \mathrm{W}$ to $126^{\circ} \mathrm{W}$, which is designated as Region 3 by Richter (1954) is discussed here, in the light of the suggested method for the prediction of the earthquakes.

Using the data in the Table 1 , the sensitive areas in the zodiac where the transits of the slow moving planets namely, Saturn, Jupiter, and Rahu display a marked association with the seismicity of this region, are presented in Table 3.

Using the favourable cosmic conditions related to seismicity of Region 3 (Table 2), the sensitive longitudes related to Region 3 are determined and are shown in Table 4. These longitudes have been found to have the traditional conjunction, square and opposition relations with the positions of planets in the foundation chart of U.S.A. prepared for 4 July, 1776 . For the transits of extremely slow moving planets namely, Pluto, Neptune and Uranus, a tolerance of $\pm 1^{\circ}$ is to be allowed and for the slow moving planets namely, Saturn, Rahu and Jupiter the tolerance is to be $\pm 2^{\circ}$. For the eaethquakes of Region 3, Saturn or Jupiter or Rahu was found to be transiting sensitive area (except in one case) and a
minimum of two slow or extremely slow moving planets were at sensitive longitudes (except on three occasions).

The sensitive areas and the sensitive longitudes for the transit of the particular planets of Groups $B$ and $A$ alongwith additional transits of the planets of Groups $C$ and $B$ which enhance the probability of occurrence are presented in Table 5.

## DISCUSSION OF PAST EARTHQUAKES AND LIMITATION OF WORK

The probability of occurrence of an earthquake, when a favourable condition is present, can be determined by the number of occasions the favourable condition occurs in a certain period and the number of occasions it is found to be associated with the occurrence of an earthquake. When two or more conditions superimpose in a small period, the combined probability can also be evaluated. In the absence of the knowledge of the probability coefficients for all favourable conditions traced, it is assumed that the probability coefficient is not less than 0.5 (as per the criterion laid down in the analysis) for all cases. In order to have a confidence level of 90 percent for any event, presence of at least FOUR favourable conditions becomes necessary. An earthquake may be predicted even when the number of superimposing favourable conditions is less than four, but it will have a lesser probability. To find out the minimum favourable conditions which can indicate the occurrence of an earthquake, those conditions present at the time of occurrence of all earthquakes of magnitude, $M \geq 7.0$ of Region 3 were determined (not being presented here). It was found that four or more conditions were present in all cases except for the earthquake of 16.12.1954. The two conditions present in this case had a probability coefficient of 0.6 and 0.67 , thus giving an acceptable compounded probability. In case of earthquakes of smaller magnitudes, all the requirements indicated were not satisfied.

Table 6 shows different overlaping favourable conditions present at time of three past earthquakes of Region 3 (the data of these earthquakes were used for fixing the favourable conditions). The data for the recent earthquake of 20.10.1989 were not used in the earlier analysis and is included in Table 6 , to show that minimum requirement is found to be satisfied in this case also. Table 6 also shows the correlation between the transits of the planets in the sensitive areas and sensitive longitudes in the zodiac, which are associated with the seismicity of the region.

The magnitudes of the earthquakes associated with the favourable conditions present can give a broad idea of magnitude of the probable earthquake. Magnitudes thus expected are also shown in Table 6 . The difference in the observed and expected magnitudes may be reduced by using an analysis in which the effect of positions of the extremely slow moving planets and their mutual relative placements are included in determining the favourable conditions. This could not be done due to

the limited time spread of the data.

## FUTURE PROBABILITY

In the monthis of January and May of 1991,. the conditions for large earthquakes will be met. However, all the requirements for the earthquake of occur in California or nearer area are not present, as only the slow (Jupiter) and extremely slow (Uranus) moving planets are transiting the sensitive areas, an earthquake of magnitude $M<7.0$ may occur in these months.

On January 1, 1991; January 10, 1991 and January 14, 1991, the favourable condition for very large earthquakes of magnitude $M \geq 7.9$ will be present and for all these favourable conditions, earthquakes were registered in Mexico ( $\mathrm{R}-5$ ). Therefore this area should expect an earthquake of magnitude M 7.5 during this period. on sept. 20-21, 1991 the conditions for occurrence of earthquakes of large magnitude ( $M \geq 7.5$ ) would be met, but the region is not clearly indicated. The details of the planetary positions for the possible occurrence of earthquakes during 1991 are presented in Table 7.

## CONCLUSION

On the basis of the foregoing study, it looks possible that, if reliable earthquake data spread over sufficiently large period say atleast 500 years is analysed, it may be possible to develop dependable earthquake prediction programmes.
